

Data Wrangling

with pandas

Cheat Sheet

<http://pandas.pydata.org>

Syntax – Creating DataFrames

	a	b	c
1	4	7	10
2	5	8	11
3	6	9	12

```
df = pd.DataFrame(
    {"a" : [4, 5, 6],
     "b" : [7, 8, 9],
     "c" : [10, 11, 12]},
    index = [1, 2, 3])
Specify values for each column.
```

```
df = pd.DataFrame(
    [[4, 7, 10],
     [5, 8, 11],
     [6, 9, 12]],
    index=[1, 2, 3],
    columns=['a', 'b', 'c'])
Specify values for each row.
```

	a	b	c
n	v		
d	1	4	7
e	2	5	11
	6	9	12

```
df = pd.DataFrame(
    {"a" : [4, 5, 6],
     "b" : [7, 8, 9],
     "c" : [10, 11, 12]},
    index = pd.MultiIndex.from_tuples(
        [('d',1),('d',2),('e',2)],
        names=['n', 'v']))
Create DataFrame with a MultiIndex
```

Method Chaining

Most pandas methods return a DataFrame so that another pandas method can be applied to the result. This improves readability of code.

```
df = (pd.melt(df)
      .rename(columns={
          'variable' : 'var',
          'value' : 'val'})
      .query('val >= 200'))
```

Tidy Data – A foundation for wrangling in pandas

In a tidy data set:

F	M	A
1	4	7
2	5	8
3	6	9

Each variable is saved in its own column

&

F	M	A
1	4	7
2	5	8
3	6	9

Each observation is saved in its own row

Tidy data complements pandas's **vectorized operations**. pandas will automatically preserve observations as you manipulate variables. No other format works as intuitively with pandas.

M	*	A
1	4	7
2	5	8
3	6	9

M * A

Reshaping Data – Change the layout of a data set

pd.melt(df)
Gather columns into rows.

pd.concat([df1, df2])
Append rows of DataFrames

df.pivot(columns='var', values='val')
Spread rows into columns.

pd.concat([df1, df2], axis=1)
Append columns of DataFrames

df=df.sort_values('mpg')
Order rows by values of a column (low to high).

df=df.sort_values('mpg', ascending=False)
Order rows by values of a column (high to low).

df=df.rename(columns = {'y': 'year'})
Rename the columns of a DataFrame

df=df.sort_index()
Sort the index of a DataFrame

df=df.reset_index()
Reset index of DataFrame to row numbers, moving index to columns.

df=df.drop(['Length', 'Height'], axis=1)
Drop columns from DataFrame

Subset Observations (Rows)

df[df.Length > 7]
Extract rows that meet logical criteria.

df.drop_duplicates()
Remove duplicate rows (only considers columns).

df.head(n)
Select first n rows.

df.tail(n)
Select last n rows.

df.sample(frac=0.5)
Randomly select fraction of rows.

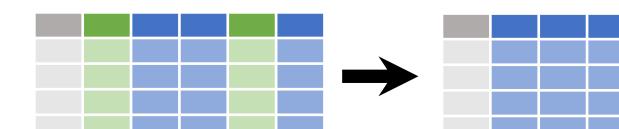

df.sample(n=10)
Randomly select n rows.

df.iloc[10:20]
Select rows by position.

df.nlargest(n, 'value')
Select and order top n entries.

df.nsmallest(n, 'value')
Select and order bottom n entries.

Subset Variables (Columns)

df[['width', 'length', 'species']]
Select multiple columns with specific names.

df['width'] or df.width
Select single column with specific name.

df.filter(regex='regex')
Select columns whose name matches regular expression regex.

regex (Regular Expressions) Examples

'.'	Matches strings containing a period '.'
'Length\$'	Matches strings ending with word 'Length'
'^Sepal'	Matches strings beginning with the word 'Sepal'
'^x[1-5]\$'	Matches strings beginning with 'x' and ending with 1,2,3,4,5
'^(?!Species\$).*''	Matches strings except the string 'Species'

df.loc[:, 'x2':'x4']
Select all columns between x2 and x4 (inclusive).

df.iloc[:, [1, 2, 5]]
Select columns in positions 1, 2 and 5 (first column is 0).

df.loc[df['a'] > 10, ['a', 'c']]
Select rows meeting logical condition, and only the specific columns .

Logic in Python (and pandas)		
<	Less than	!=
>	Greater than	df.column.isin(values)
==	Equals	pd.isnull(obj)
<=	Less than or equals	pd.notnull(obj)
>=	Greater than or equals	&, , ~, ^, df.any(), df.all()
		Not equal to
		Group membership
		Is NaN
		Is not NaN
		Logical and, or, not, xor, any, all

Summarize Data

`df['Length'].value_counts()`
Count number of rows with each unique value of variable

`len(df)`
of rows in DataFrame.

`len(df['w'].unique())`
of distinct values in a column.

`df.describe()`
Basic descriptive statistics for each column (or GroupBy)

pandas provides a large set of **summary functions** that operate on different kinds of pandas objects (DataFrame columns, Series, GroupBy, Expanding and Rolling (see below)) and produce single values for each of the groups. When applied to a DataFrame, the result is returned as a pandas Series for each column. Examples:

<code>sum()</code>	<code>min()</code>
Sum values of each object.	Minimum value in each object.
<code>count()</code>	<code>max()</code>
Count non-NA/null values of each object.	Maximum value in each object.
<code>median()</code>	<code>mean()</code>
Median value of each object.	Mean value of each object.
<code>quantile([0.25,0.75])</code>	<code>var()</code>
Quantiles of each object.	Variance of each object.
<code>apply(function)</code>	<code>std()</code>
Apply function to each object.	Standard deviation of each object.

Group Data

`df.groupby(by="col")`
Return a GroupBy object, grouped by values in column named "col".

`df.groupby(level="ind")`
Return a GroupBy object, grouped by values in index level named "ind".

All of the summary functions listed above can be applied to a group.

Additional GroupBy functions:

`size()`
Size of each group.

`agg(function)`
Aggregate group using function.

Windows

`df.expanding()`
Return an Expanding object allowing summary functions to be applied cumulatively.

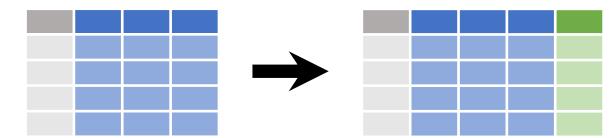

`df.rolling(n)`
Return a Rolling object allowing summary functions to be applied to windows of length n.

Handling Missing Data

`df=df.dropna()`
Drop rows with any column having NA/null data.

`df=df.fillna(value)`
Replace all NA/null data with value.

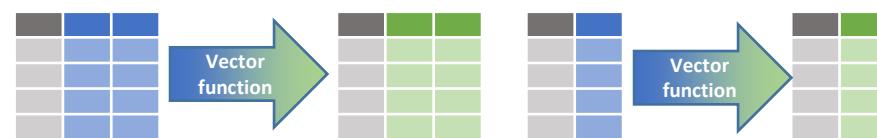

Make New Variables

`df=df.assign(Area=lambda df: df.Length*df.Height)`
Compute and append one or more new columns.

`df['Volume'] = df.Length*df.Height*df.Depth`
Add single column.

`pd.qcut(df.col, n, labels=False)`
Bin column into n buckets.

pandas provides a large set of **vector functions** that operate on all columns of a DataFrame or a single selected column (a pandas Series). These functions produce vectors of values for each of the columns, or a single Series for the individual Series. Examples:

`max(axis=1)` Element-wise max.
`min(axis=1)` Element-wise min.

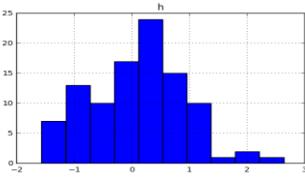

`clip(lower=-10,upper=10)` `abs()`
Trim values at input thresholds Absolute value.

The examples below can also be applied to groups. In this case, the function is applied on a per-group basis, and the returned vectors are of the length of the original DataFrame.

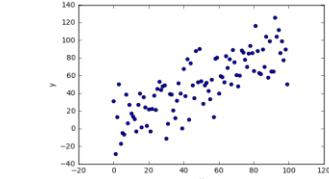

<code>shift(1)</code>	<code>shift(-1)</code>
Copy with values shifted by 1.	Copy with values lagged by 1.
<code>rank(method='dense')</code>	<code>cumsum()</code>
Ranks with no gaps.	Cumulative sum.
<code>rank(method='min')</code>	<code>cummax()</code>
Ranks. Ties get min rank.	Cumulative max.
<code>rank(pct=True)</code>	<code>cummin()</code>
Ranks rescaled to interval [0, 1].	Cumulative min.
<code>rank(method='first')</code>	<code>cumprod()</code>
Ranks. Ties go to first value.	Cumulative product.

Plotting

`df.plot.hist()`
Histogram for each column

`df.plot.scatter(x='w',y='h')`
Scatter chart using pairs of points

Combine Data Sets

adf
x1
A
B
C

bdf
x1
A
B
D

Standard Joins

x1	x2	x3
A	1	T
B	2	F
C	3	NaN

`pd.merge(adf, bdf, how='left', on='x1')`
Join matching rows from bdf to adf.

x1	x2	x3
A	1.0	T
B	2.0	F
D	NaN	T

`pd.merge(adf, bdf, how='right', on='x1')`
Join matching rows from adf to bdf.

x1	x2	x3
A	1	T
B	2	F

`pd.merge(adf, bdf, how='inner', on='x1')`
Join data. Retain only rows in both sets.

x1	x2	x3
A	1	T
B	2	F
C	3	NaN
D	NaN	T

x1	x2
A	1
B	2

`adf[adf.x1.isin(bdf.x1)]`
All rows in adf that have a match in bdf.

x1	x2
C	3

`adf[~adf.x1.isin(bdf.x1)]`
All rows in adf that do not have a match in bdf.

ydf
x1
A
B

zdf
x1
B
C
D

Set-like Operations

x1	x2
B	2
C	3

`pd.merge(ydf, zdf)`
Rows that appear in both ydf and zdf (Intersection).

x1	x2
A	1
B	2
C	3
D	4

`pd.merge(ydf, zdf, how='outer')`
Rows that appear in either or both ydf and zdf (Union).

x1	x2
A	1

`pd.merge(ydf, zdf, how='outer', indicator=True)`
.query('_merge == "left_only"')
.drop(['_merge'], axis=1)
Rows that appear in ydf but not zdf (Setdiff).
